

Logical Reasoning

Placement Training Program

Puzzles

Logic puzzles present a set of constraints (statements that must all be simultaneously true) and ask you to determine the one arrangement or set of facts satisfying every constraint at once. The most reliable approach is systematic elimination: build a grid or table of every possibility, and work through constraints one at a time, ruling out combinations that violate each one, rather than trying to jump to the answer by intuition — intuition is exactly what these puzzles are designed to mislead.

Seating Arrangements

Seating arrangement problems (linear and circular) test the same systematic constraint-satisfaction skill as general puzzles, with the added wrinkle of spatial relationships — 'to the left of,' 'immediately next to,' 'opposite' (in circular arrangements). Drawing the arrangement out and updating it as each clue is applied, rather than trying to hold it all in your head, is the single most effective technique for solving these accurately under time pressure.

Blood Relations

Blood relation questions chain together family relationship statements ('A is B's mother's brother') and ask you to determine the final relationship between two people. The practical technique is drawing a simple family tree diagram as each relationship is stated, rather than trying to track the chain mentally — these problems are specifically designed to overload working memory if attempted without a visual aid, and become mechanical once drawn out.

Syllogisms

Syllogisms present two or more statements (premises) and ask which conclusions necessarily follow. The key skill is distinguishing between what must be true given the premises versus what merely could be true or sounds plausible — syllogism questions are deliberately constructed with tempting-but-invalid conclusions. Venn diagrams are the standard tool: drawing out each premise as overlapping/separate circles makes it visually clear which conclusions are actually guaranteed by the diagram versus which just seem intuitively likely.

Coding-Decoding

Coding-decoding questions establish a pattern that transforms letters, numbers, or words (e.g. each letter shifted forward by a fixed number of positions in the alphabet) and ask you to apply or reverse that pattern. The approach is to identify the transformation rule from the given example first — checking it against every letter/number in the example, not just the first one — before applying that same confirmed rule to the new case being asked about.
