

Non-Verbal Reasoning

Placement Training Program

Series Completion

Series completion questions present a sequence of shapes or figures following a hidden rule and ask what comes next. The systematic approach: check each figure against the previous one for a consistent, single type of change — rotation by a fixed angle, an added/removed element, a consistent shading pattern, or a repeating cycle of a small number of distinct figures — rather than trying to see the whole pattern at once. Most series use exactly one consistent transformation rule; if a hypothesis doesn't hold for all pairs in the sequence, it's the wrong rule, not an exception.

Pattern Recognition

Pattern recognition questions (matrix completion, figure grouping) ask you to identify what property groups a set of figures together, or what's missing from a grid following row/column rules. The technique that works consistently: examine rows and columns of a matrix separately for their own individual pattern (since many matrix questions apply a different rule down each column, or a compounding rule across both dimensions at once) rather than searching for one single rule across the whole grid immediately.

Mirror & Water Images

Mirror image questions ask what a figure looks like reflected in a vertical mirror (left-right reversed); water image questions ask for a horizontal reflection (up-down reversed, as if reflected in still water below the figure). The most reliable technique, especially for figures containing letters or numbers, is checking each individual element's orientation after reflection separately, since a full-figure reflection needs to be applied consistently to every component — errors usually come from correctly flipping the overall figure but forgetting to also flip small details inside it.

Cubes & Dice

Cube and dice questions test 3D spatial visualization — given a few views of a cube or a net (unfolded cube layout), determine what's on a hidden face, or how many smaller cubes have a given number of painted faces after a larger cube is cut up. The systematic technique for net-folding questions: identify which faces are opposite each other on the net first (opposite faces are never adjacent on a correctly-folded cube), since that single fact — established once — answers most of the specific questions asked about that cube.
