

Quantitative Aptitude

Placement Training Program

Number Systems

Number system questions test fluency with integers, factors, multiples, divisibility rules, and remainders — the building blocks nearly every other quant topic builds on. Fast divisibility checks (a number is divisible by 3 if its digit sum is divisible by 3; by 9 similarly; by 4 if its last two digits form a number divisible by 4) save significant time versus doing full division, and are worth memorizing cold rather than re-deriving under time pressure.

Percentages & Ratios

Percentage and ratio problems are really the same underlying relationship expressed differently, and most placement-test questions in this area are word problems requiring translating a real-world scenario into the correct equation. A percentage increase followed by an equal percentage decrease does not return to the original value (e.g. a 20% increase followed by a 20% decrease results in a net 4% decrease) — this specific 'gotcha' appears constantly in aptitude tests specifically because it trips up people relying on intuition instead of working the actual numbers.

Time, Speed & Distance

These problems rest on one core relationship — $\text{distance} = \text{speed} \times \text{time}$ — applied across scenarios like relative speed (two objects moving toward or away from each other), average speed (which is NOT simply the average of two speeds when time, not distance, is held constant across the two legs — a very common trap), and problems involving trains, boats/streams (where current speed adds or subtracts from the boat's own speed depending on direction), and circular tracks.

Profit & Loss

Profit and loss problems apply percentage reasoning to buying/selling scenarios: profit or loss is always calculated as a percentage of the cost price, not the selling price, unless a question explicitly states otherwise — a distinction that changes the answer and is a frequent source of errors when read too quickly. Marked price, discount, and successive discounts (which combine the same way successive percentage changes do, not by simply adding the two discount percentages) round out the core vocabulary this topic is tested with.

Data Interpretation

Data interpretation questions present information as tables, bar charts, pie charts, or line graphs and ask questions requiring you to extract and combine specific values — testing accurate reading under time pressure as much as calculation. The practical strategy: read the question being asked before diving into the chart, so you know exactly which numbers to look for instead of trying to absorb the whole chart upfront; and for pie charts specifically, remember that segments show proportions, so converting to actual values requires knowing (or calculating) the total.
